

Question 20. Write four informations about the reaction:

Answer: Let x be the O.N. of C.

O.N. of C in cyanogen, $(\text{CN})_2 = 2(x - 3) = 0$ or $x = +3$

O.N. of C in cyanide ion, $\text{CN}^- = x - 3 = -1$ or $x = +2$

O.N. of C in cyanate ion, $\text{CNO}^- = x - 3 - 2 = -1$ or $x = +4$

The four information about the reaction are:

- (i) The reaction involves decomposition of cyanogen, $(\text{CN})_2$ in the alkaline medium to cyanide ion, CN^- and cyanate ion, CNO^- .
- (ii) The O.N. of C decreases from +3 in $(\text{CN})_2$ to +2 in CN^- ion and increases from +3 in $(\text{CN})_2$ to +4 in CNO^- ion. Thus, cyanogen is simultaneously reduced to cyanide ion and oxidised to cyanate ion.
- (iii) It is an example of a redox reaction in general and a disproportionation reaction in particular.
- (iv) Cyanogen is a pseudohalogen (behaves like halogens) while cyanide ion is a pseudohalide ion (behaves like halide ion).

Question 21. The Mn^{3+} ion is unstable in solution and undergoes disproportionation to give Mn^{2+} , MnO_2 and H^+ ion. Write a balanced ionic equation for the reaction.

Answer:

The skeletal equation is:

Oxidation half equation:

Balance O.N. by adding electrons,

Balance charge by adding 4H^+ ions,

Balance O atoms by adding $2\text{H}_2\text{O}$:

Reduction half equation:

Balance O.N. by adding electrons:

Adding Eq. (i) and Eq. (ii), the balanced equation for the disproportionation reaction is

Question 22. Consider the elements: Cs, Ne, I, F

- (a) Identify the element that exhibits -ve oxidation state.
- (b) Identify the element that exhibits +ve oxidation state.
- (c) Identify the element that exhibits both +ve and -ve oxidation states.
- (d) Identify the element which neither exhibits -ve nor +ve oxidation state.

Answer:

- (a) F. Fluorine being the most electronegative element shows only a -ve oxidation state of -1.
- (b) Cs. Alkali metals because of the presence of a single electron in the valence shell, exhibit an oxidation state of +1.
- (c) I. Because of the presence of seven electrons in the valence shell, I shows an oxidation state of -1 (in compounds of I with more electropositive elements such as H, Na, K, Ca, etc.) or an oxidation

state of +1 compounds of I with more electronegative elements, i.e., O, F, etc.) and because of the presence of d-orbitals it also exhibits +ve oxidation states of +3, +5 and +7.

(d) Ne. It is an inert gas (with high ionization enthalpy and high positive electron gain enthalpy) and hence it neither exhibits -ve nor +ve oxidation states.

Question 23. Chlorine is used to purify drinking water. Excess of chlorine is harmful. The excess chlorine is removed by treating with sulphur dioxide. Present a balanced equation for the reaction for this redox change taking place in water.

Answer: The skeletal equation is:

Reduction half equation:

Balance O.N. by adding electrons:

Oxidation half equation:

Balance O.N. by adding electrons:

Balance charge by adding 4H^+ ions:

Balance O atoms by adding $2\text{H}_2\text{O}$,

Adding Eq. (i) and Eq. (ii), we have,

This represents the balanced redox reaction.

Question 24. Refer to the periodic table given in your book and now answer the following questions.

(a) Select the possible non-metals that can show disproportionation reaction.

(b) Select three metals that show disproportionation reaction.

Answer:

(a) The non-metals are: P_4 , Cl_2 and S_8 .

(b) The metals are: Cu^+ , Ga^+ , In^+ , Mn^{3+} , etc.

Question 25. In Ostwald's process for the manufacture of nitric acid, the first step involves the oxidation of ammonia gas by oxygen gas to give nitric oxide gas and steam. What is the maximum weight of nitric oxide that can be obtained starting only with 10.0 g of ammonia and 20.0 g of oxygen?

Answer: The balanced equation for the reaction is:

Here, 68 g of NH_3 will react with $\text{O}_2 = 160 \text{ g}$

$$\therefore 10 \text{ g of } \text{NH}_3 \text{ will react with } \text{O}_2 = \frac{160 \text{ g}}{68 \text{ g}} \times 10 \text{ g} = 23.6 \text{ g}$$

But the amount of O_2 which is actually available is 20.0 g which is less than the amount which is needed. Therefore, O_2 is the limiting reagent and hence calculations must be based upon the amount of

O₂ taken and not on the amount of NH₃ taken. From the equation,
 160 g of O₂ produce NO = 120 g
 20 g of O₂ will produce NO = 120/160 × 20 = 15 g

Question 26. Using the standard electrode potentials given in the Table 8.1, predict if the reaction between the following is feasible:

- (a) Fe³⁺(aq) and I⁻(aq)
- (b) Ag⁺(aq) and Cu(s)
- (c) Fe³⁺(aq) and Cu(s)
- (d) Ag(s) and Fe³⁺(aq)
- (e) Br₂(aq) and Fe³⁺(aq).

Answer:

(a) It may be noted that for oxidation reactions, i.e., Eq. (i), the sign of the electrode potential as given in Table 8.1 is reversed. To get the equation for the overall reaction, the number of electrons lost in Eq. (i) and gained in Eq. (ii) must be cancelled. To do so, Eq. (ii) is multiplied by 2 and added to Eq. (i). Further, it may be noted that whenever any half reaction equation is multiplied by any integer, its electrode potential is not multiplied by that integer. Thus,

Overall reaction: 2Fe³⁺(aq) + 2I⁻(aq) → 2Fe²⁺(aq) + I₂(s); E° = + 0.23 V

Since the EMF for the above reaction is positive, therefore, the above reaction is feasible.

(b) The possible reaction between Ag⁺(aq) and Cu(s) is Cu(s) + 2Ag⁺(aq) → Cu²⁺(aq) + 2Ag(s)

The above redox reaction can be split into the following two half reactions. Writing electrode potential for each half reaction from Table 8.1, we have,

Overall reaction: Cu(s) + 2Ag⁺(aq) → Cu²⁺(aq) + 2Ag(s); E° = +0.46 V

Since the EMF of the above reaction comes out to be **positive**, therefore, the above reaction is feasible.

- (c) Suppose the reaction between Fe³⁺(aq) and Cu(s) occurs according to the following equation.

The above reaction can be split into the following two half reactions. Writing electrode potential for each half reaction from Table 8.1, we have,

Overall reaction: Cu(s) + 2Fe³⁺(aq) → Cu²⁺(aq) + 2Fe²⁺(aq); E° = +0.43 V

Since the EMF of the reaction is positive, therefore, the above reaction is feasible.

Alternatively, if the reaction between Fe³⁺(aq) and Cu(s) occurs according to the following equation.

The EMF of the reaction comes out to be -ve, i.e., -0.376 V (-0.34 V - 0.036 V) and hence this reaction is not feasible.

- (d) Suppose the reaction between Ag(s) and Fe³⁺(aq) occurs according to the following equation:

The above reaction can be split into the following two half reactions. Writing electrode potential for each half reaction from Table 8.1, we have,

Overall reaction: Ag(s) + Fe³⁺(aq) → Ag⁺(aq) + Fe²⁺(aq); E° = -0.03 V

Since the EMF of the reaction is **negative**, therefore, the above reaction is not feasible.

Alternatively, the reaction between Ag(s) and Fe³⁺(aq) may occur according to the following equation

On similar lines, we can calculate the e.m.f. of this reaction comes to be even more **negative**, i.e., -0.836 V, and hence this redox reaction is also not feasible.

- (e) Suppose the reaction between Br₂(aq) and Fe²⁺(aq) occurs according to the following equation:

The above reaction can be split into the following two half reactions. Writing electrode potential for each half reaction from the Table 8.1, we have

Overall reaction: 2Fe²⁺(aq) + Br₂(aq) → 2Fe³⁺(aq) + 2Br⁻(aq); E° = +0.32 V

Since the EMF for the above reaction is **positive**, therefore, this reaction is feasible.

Question 27. Predict the products of electrolysis in each of the following:

(i) An aqueous solution of AgNO_3 with silver electrodes.

(ii) An aqueous solution of silver nitrate with platinum electrodes.

(iii) A dilute solution of H_2SO_4 with platinum electrodes.

(iv) An aqueous solution of CuCl_2 with platinum electrodes.

Answer: (i) In aqueous solution, AgNO_3 ionises to give $\text{Ag}^+(\text{aq})$ and $\text{NO}_3^-(\text{aq})$ ions.

Thus, when electricity is passed, $\text{Ag}^+(\text{aq})$ ions move towards the cathode while $\text{NO}_3^-(\text{aq})$ ions move towards the anode. In other words, at the cathode, either $\text{Ag}^+(\text{aq})$ ions or H_2O molecules may be reduced. Which of these will actually get discharged would depend upon their electrode potentials which are given below:

Since the electrode potential (i.e., reduction potential of $\text{Ag}^+(\text{aq})$ ions is higher than that of H_2O molecules, therefore, at the cathode, it is the $\text{Ag}^+(\text{aq})$ ions (rather than H_2O molecules) which are reduced.

Similarly, at the anode, either Ag metal of the anode or H_2O molecules may be oxidised. Their electrode potentials are:

Since the oxidation potential of Ag is much higher than that of H_2O , therefore,

at the anode, it is the Ag of the silver anode which gets oxidised and not the H_2O molecules. It may, however, be mentioned here that the oxidation potential of NO_3^- ions is even lower than that of H_2O since more bonds are to be broken during reduction of NO_3^- ions than those in H_2O .

Thus, when an aqueous solution of AgNO_3 is electrolysed, Ag from Ag anode dissolves while $\text{Ag}^+(\text{aq})$ ions present in the solution get reduced and get deposited on the cathode.

(ii) If, however, electrolysis of AgNO_3 solution is carried out using platinum electrodes, instead of silver electrodes, oxidation of water occurs at the anode since Pt being a noble metal does not undergo oxidation easily. As a result, O_2 is liberated at the anode according to equation (iv).

Thus, when an aqueous solution of AgNO_3 is electrolysed using platinum electrodes, Ag^+ ions from the solution get deposited on the cathode while O_2 is liberated at the anode.

(iii) In aqueous solution, H_2SO_4 ionises to give $\text{H}^+(\text{aq})$ and $\text{SO}_4^{2-}(\text{aq})$ ions.

Thus, when electricity is passed, $\text{H}^+(\text{aq})$ ions move towards cathode while $\text{SO}_4^{2-}(\text{aq})$ ions move towards anode. In other words either $\text{H}^+(\text{aq})$ ions or H_2O molecules are reduced. Their electrode

Since the electrode potential (i.e., reduction potential) of $\text{H}^+(\text{aq})$ ions is higher than that of H_2O , therefore, at the cathode, it is $\text{H}^+(\text{aq})$ ions (rather than H_2O molecules) which are reduced to evolve H_2 gas.

Similarly at the anode, either $\text{SO}_4^{2-}(\text{aq})$ ions or H_2O molecules are oxidised. Since the oxidation potential of SO_4 is expected to be much lower (since it involved cleavage of many bonds as

compared to those in H₂O) than that of H₂O molecules, therefore, at the anode, it is H₂O molecules (rather than SO₄²⁻ ions) which are oxidised to evolve O₂ gas.

From the above discussion, it follows that during electrolysis of an aqueous solution of H₂SO₄ only the electrolysis of H₂O occurs liberating H₂ at the cathode and O₂ at the anode.

(iv) In aqueous solution, CuCl₂ ionises as follows:

On passing electricity, Cu²⁺(aq) ions move towards cathode and Cl⁻(aq) ions move towards anode.

Thus, at cathode, either Cu²⁺(aq) or H₂O molecules are reduced.

Their electrode potentials are:

Since the electrode potential of Cu²⁺(aq) ions is much higher than that of H₂O, therefore, at the cathode, it is Cu²⁺(aq) ions which are reduced and not H₂O molecules.

Similarly, at the anode, either Cl⁻(aq) ions or H₂O molecules are oxidised. Their oxidation potentials

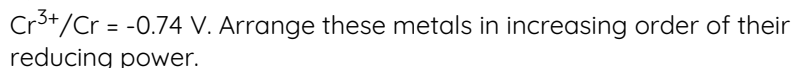

Although oxidation potential of H₂O molecules is higher than that of Cl⁻ ions, nevertheless, oxidation of Cl⁻(aq) ions occurs in preference to H₂O since due to overvoltage much lower potential than -1.36 V is needed for the oxidation of H₂O molecules.

Thus, when an aqueous solution of CuCl₂ is electrolysed, Cu metal is liberated at the cathode while Cl₂ gas is evolved at the anode.

Question 28. Arrange the following metals in the order in which they displace each other from the solution of their salts. Al, Cu, Fe, Mg and Zn.

Answer: It is based upon the relative positions of these metals in the activity series. The correct order is Mg, Al, Zn, Fe, Cu.

Question 29. Given the standard electrode potentials,

Answer: Lower the electrode potential, better is the reducing agent.

Since the electrode potentials increase in the order; K⁺/K (-2.93 V), Mg²⁺/Mg (-2.37 V), Cr³⁺/Cr (-0.74 V), Hg²⁺/Hg (0.79 V), Ag⁺/Ag (0.80 V), therefore, reducing power of metals decreases in the same order, i.e., K, Mg, Cr, Hg, Ag.

Question 30. Depict the galvanic cell in which the reaction, Zn(s) + 2Ag⁺(aq) → Zn²⁺(aq) + 2Ag(s) takes place. Further show:

(i) which of the electrode is negatively charged.

(ii) the carriers of current in the cell and

(iii) individual reaction at each electrode.

Answer: The given redox reaction is Zn(s) + 2Ag⁺(aq) → Zn²⁺(aq) + 2Ag(s)

Since Zn gets oxidised to Zn²⁺ ions, and Ag⁺ gets reduced to Ag metal, therefore,

oxidation occurs at the zinc electrode and reduction occurs at the silver electrode. Thus, galvanic cell corresponding to the above redox reaction may be depicted as:

- (i) Since oxidation occurs at the zinc electrode, therefore, electrons accumulate on the zinc electrode and hence, *zinc electrode is negatively charged*.
- (ii) The ions carry current. The electrons flow from Zn to Ag electrode while the current flows from Ag to Zn electrode.
- (iii) The reactions occurring at the two electrodes are:
