

Triangles Ex 4.7 Q22

Answer :

It is given that $\triangle ABC$ is a right-angled at C and D is the mid-point of BC.

In the right angled triangle ADC, we will use Pythagoras theorem,

$$AD^2 = DC^2 + AC^2 \dots\dots\dots(1)$$

Since D is the midpoint of BC, we have

$$DC = \frac{BC}{2}$$

Substituting $DC = \frac{BC}{2}$ in equation (1), we get

$$AD^2 = \left(\frac{BC}{2}\right)^2 + AC^2$$

$$AD^2 = \frac{BC^2}{4} + AC^2$$

$$4AD^2 = BC^2 + 4AC^2$$

$$BC^2 = 4AD^2 - 4AC^2$$

$$BC^2 = 4(AD^2 - AC^2)$$

Triangles Ex 4.7 Q23

Answer :

In order to prove angle $\angle ACD = 90^\circ$ it is enough to prove that $AD^2 = AC^2 + CD^2$.

Given, $AD^2 = AB^2 + BC^2 + CD^2$

$$AD^2 - CD^2 = AB^2 + BC^2 \quad \dots(1)$$

Since $\angle B = 90^\circ$, so applying Pythagoras theorem in the right angled triangle ABC, we get

$$AC^2 = AB^2 + BC^2 \quad \dots(2)$$

From (1) and (2), we get

$$AC^2 = AD^2 - CD^2$$

$$AC^2 + CD^2 = AD^2$$

Therefore, angle $\boxed{\angle ACD = 90^\circ}$. (Converse of pythagoras theorem)
