

Circles Ex 16.5 Q14

Answer :

It is given that, O is the center of the circle and $\angle AEC = 30^\circ$

We have to find the value of $\angle y$ and $\angle z$

Since angle in the same segment are equal

So $\angle AEC = \angle ADC = 30^\circ$

And $\angle z = 30^\circ$ Because same arc subtend same angle on the circumference of the same circle.

Since $\angle AOC = 2\angle ADC$ ($\angle y$ is at center)

As angle subtended by a arc on the center is double the angle subtended at the circumference.

Then

$$\begin{aligned} y &= 2\angle z \\ &= 2 \times 30^\circ (\angle z = 30^\circ) \\ &= 60^\circ \end{aligned}$$

Now since angle in alternate segment are complementary

So

$$\begin{aligned} \angle z + \angle x &= 180^\circ \\ \angle x &= 180^\circ - \angle z \\ \angle x &= (180^\circ - 30^\circ) (\text{Since } \angle z = 30^\circ) \\ \Rightarrow \angle x &= 150^\circ \end{aligned}$$

Hence

$$\boxed{\angle x = 150^\circ}$$

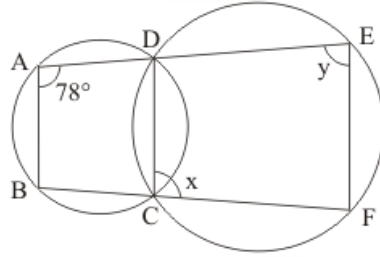

$$\boxed{\angle y = 60^\circ}$$

and $\boxed{\angle z = 30^\circ}$

Circles Ex 16.5 Q15

Answer :

It is given that, $\angle A = 78^\circ$ and $ABCD$, $DCFE$ are cyclic quadrilateral

We have to find $\angle x$ and $\angle y$

Since $ABCD$ is cyclic quadrilateral

So $\angle A + \angle BCD = 180^\circ$ (opposite angle of a cyclic quadrilateral are supplementary)

$$\angle BCD = 180^\circ - \angle A (\angle A = 78^\circ)$$

$$\angle BCD = 180^\circ - 78^\circ$$

$$\angle BCD = 102^\circ \dots\dots (1)$$

Total angle at point C is 180° (BF is straight line)

So

$$\angle BCD + \angle DCF = 180^\circ$$

$$\angle DCF = 180^\circ - \angle BCD$$

$$\angle x = 180^\circ - 102^\circ$$

$$= 78^\circ$$

Now in cyclic quadrilateral $DCFE$

$$\angle x + \angle y = 180^\circ$$

$$\angle y = 180^\circ - 78^\circ \text{ (opposite angle of a cyclic quadrilateral are supplementary)}$$

$$= 102^\circ$$

Hence $\boxed{\angle x = 78^\circ}$ and $\boxed{\angle y = 102^\circ}$
